# **Exercise: Exceptions and Error Handling**

This document defines the lab for "Java OOP" course @ Software University.

# **Problem 1. Square Root**

Write a program that reads an integer **number** and **calculates** and **prints** its **square root**. If the number is invalid, print **"Invalid number"**. In all cases finally print **"Good bye"**. Use **try-catch-finally**.

#### **Problem 2. Enter Numbers**

Write a method **printNumbers(int start, int end)** that prints an integer numbers in a given range [**start...end**]. If an **invalid number** or a **non-number** text is entered, the method should **throw an exception**. Using this method write a program that enters **start** and **end**: **1** < **start** < **end** < **100**. If the user enters an invalid number, make the user enter all of them again.

# **Problem 3. Fixing**

This program is throwing an **ArrayIndexOutOfBoundsException**. Using your skills, fix this problem using a try catch block.

```
public static void main(String[] args) {
    Scanner scanner = new Scanner(System.in);
    String[] weekdays = new String[5];

    weekdays[0] = "Monday";
    weekdays[1] = "Tuesday";
    weekdays[2] = "Wednesday";
    weekdays[3] = "Thursday";
    weekdays[4] = "Friday";

    for (int i = 0; i <= weekdays.length; i++) {
        System.out.println(weekdays[i]);
    }

    scanner.nextLine();
}</pre>
```

### Problem 4. Valid Person

Define a simple class **Person**, which has the following fields: **first name**, **last name** and **age**. **Validate** the data in the **setters**, **throw** appropriate **exceptions** in case invalid data is entered.

# Step 1. Create a Class Person

Create a class **Person**. The class should contain the following fields: **first name (String), last name (String)** and age (int).

All fields are required, meaning you should have one constructor accepting all three as parameters. For example:

© <u>Software University Foundation</u>. This work is licensed under the <u>CC-BY-NC-SA</u> license.

Follow us: (😥

```
public class Person {
    private String firstName;
    private String lastName;
    private int age;

public Person(String firstName, String lastName, int age) {
        // TODO: add setters and validate data
    }

    //TODO: add getters and setters
}
```

# Step 2. Add Getters and Setters and Validate the Data

Add a **getters and setters** for each of the fields. Perform validations in their **setters** to keep the state of the **Person** objects correct.

The first and last name cannot be null or empty strings. To check this, use the string.IsNullOrEmpty() method.

The age must be in the range [0 ... 120].

If invalid data is entered, **throw** appropriate exceptions with descriptive **messages**. E.g., if an empty name is entered, an appropriate exception may be **IllegalArgumentException**.

Example for validating the first name (last name is analagous):

```
private void setFirstName(String firstName) {
   if (firstName.isBlank()) {
      throw new IllegalArgumentException("The first name cannot be null or empty");
   }
   this.firstName = firstName;
}
```

Example for validating the age:

```
private void setAge(int age) {
   if (age < 0 || age > 120) {
      throw new IllegalArgumentException("Age should be in the range [0 ... 120]");
   }
   this.age = age;
}
```

Now the constructor should make use of the setters instead of modifying the private fields directly:

```
public Person(String firstName, String lastName, int age) {
    this.setFirstName(firstName);
    this.setLastName(lastName);
    this.setAge(age);
}
```

# **Step 3. Test the Person Class**

In your main program, test whether your class behaves properly. Create several objects of type Person – one with valid data, one with an empty first name, one with null as last name, one with negative age and one with age > 120.

Check whether executing the code results in errors, when bad data is provided. Test the invalid cases one by one by commenting out the other invalid lines of code (your program will stop executing when the first error is encountered).

```
public static void main(String[] args) {
    Person peter = new Person(firstName: "Franco", lastName: "Aimee", age: 19);

    Person noName = new Person(firstName: " ", lastName: "Aimee", age: 19);
    Person noLastName = new Person(firstName: "Franco", lastName: null, age: 19);
    Person negativeAge = new Person(firstName: "Franco", lastName: "Aimee", age: -1);
    Person tooOldForThisProgram = new Person(firstName: "Franco", lastName: "Aimee", age: 121);
}
```

#### Step 4. Add Try-Catch Blocks

To prevent the program from blowing up, surround the invalid lines in **try-catch** blocks. It's a good practice to put different catch blocks for the different types of errors you anticipate the operation might throw. Print the **message** of the exception in the catch block.

#### Example:

```
try {
    Person noName = new Person(firstName: " ", lastName: "Aimee", age: 19);
} catch (IllegalArgumentException ex) {
    System.out.println("Exception thrown: " + ex.getMessage());
}

// Result in console:
// Exception thrown: The first name cannot be null or empty
```

# **Problem 5. Custom Exception**

Create InvalidPersonNameException class in the previous problem, which does not allow any special character or numeric value in a name of any of the students. To do that create **Student** class with name and email fields. When trying to create student with name "4havdar", throw your custom Exception class.
